	• Frequently Asked Question
	he LENR phenomena.
	Through the history of physics every particle has demonstrits existence by the phenomena it explains.
Why	is it necessary to load a Pd cathode?
Т	o prevent loss of D into Pd.
	Here's why:
	Electrolysis generates deuterium at the electrolyte-palladiu interface.
	Deuterium is soluble in a palladium cathode and diffuses ir
	Deuterium concentration in the electrolyte remains low. Bu formation and growth are inhibited and there is little fluid shear.
	LENR is suppressed.
	Only after the palladium is saturated does deuterium rema the electrolyte and support the bubble growth and fluid sh required for LENR.
How	do you explain H + Ni reaction?
Т	he reaction is not nuclear.
	(See next panel.)

## vtic LENR Reactions

growth examples cerium

- by environment  $^{2}\text{H} + ^{A}\textbf{n} \rightarrow ^{A+1}\textbf{n} + ^{1}\text{H}$  $^{2}\text{H} + ^{A+1}\textbf{n} \rightarrow ^{A+2}\textbf{n} + ^{1}\text{H}$  $^{2}\text{H} + ^{A+2}\textbf{n} \rightarrow ^{A+3}\textbf{n} + ^{1}\text{H}$  $^{2}\text{H} + ^{A+3}\text{n} \rightarrow ^{A+4}\text{n} + ^{1}\text{H}$ pe beta decay examples iced by environment  $^{A}\mathbf{n} \rightarrow ^{A}\mathbf{H}$ 
  - $^{A}H \rightarrow ^{A}He$
- $^{A}\text{He} \rightarrow ^{A}\text{Li}$
- pe alpha decay examples iced by environment
  - <sup>A</sup>He  $\rightarrow$  <sup>A-4</sup>n + <sup>4</sup>He
    - $^{A}Li \rightarrow ^{A-4}H + {}^{4}He$

## ron Isotope Fission

y reactions conserve symmetric isotope number. rease by escape of  ${}^{A}\mathbf{n}$  from reactor.

- essential to build up and maintain <sup>A</sup>**n** population:
- $(A+B+C)\mathbf{n} + DZ \rightarrow A\mathbf{n} + B\mathbf{n} + C+DZ.$
- leons from symmetric isotopes.
- than gain from growth reaction. tion of catalyst precursor <sup>D</sup>Z must be small.

### **7.** Role of Fluid Shear 1. Fleischmann-Pons reactor produces D in solution at cathode. Solution becomes supersaturated with D. 2.Bubbles of D are nucleated at cathode irregularities. Symmetric isotopes are weakly bound. Rapid bubble growth drives high shear rate in electrolyte. Their vibrations have low energy levels and are closely spaced. 3.Shear deformation brings potential reactants together. Their excitations can be understood as nuclear phonons. Much faster than diffusion. They absorb reaction energy and become hot. 4. Neutron isotope growth rate is dramatically increased. Kinetic energies of reaction products are negligible. 5. Temperature of electrolyte rises rapidly. Causes a flash of radiant heat. Enough to melt palladium cathode surface. A micro-explosion. 6.Bubble nucleation site is blown clear of electrolyte. Electrolysis is interrupted at that site. The site cools down, electrolyte returns, electrolysis resumes. 7. Another LENR cycle produces another reaction flash. $^{A+4}\mathbf{n} \rightarrow ^{A+4}\mathbf{He}$ Sparkling thermal energy flashes cover the cathode surface. $^{A+4}$ **He** $\rightarrow$ $^{A}$ **n** + $^{4}$ He **18.** Heat after Death 21 MeV per <sup>4</sup>He (agrees with experiment). **Pons and Fleishmann** Mizuno $4(^{1}\text{H})$ per $^{4}\text{He}$ (predicted ratio not yet measured). Electrolytic D/Pd reactor Electrolytic D/Pd reactor Boils dry (death) Turns off power (death) No fluid shear Fluid shear continues No growth reaction Growth reaction continues Beta and alpha decays continue Beta and alpha decays continue **n** concentration stabilizes **n** concentration drops to zero **Reaction continues** Reaction stops $^{A}\mathbf{n} + ^{23}Na \rightarrow ^{27}Na(300ms) + ^{A-4}\mathbf{n} + 10$ MeV thermal energy Heat after death lifetime Heat after death lifetime $^{27}$ Na $\rightarrow ^{27}$ Mg(9.5min) + 9 MeV kinetic energy about 3 hours more than 5 days $^{27}Mg \rightarrow ^{27}Al(stable) + 2.5 MeV kinetic energy$

# **||4. Hegelstein Criterion The criterion:** Kinetic energies of LENR products are negligible. **The theory:** Every LENR reaction has a symmetric isotope product. **Conclusion**: The Hegelstein criterion is met. **5.** Heat and Helium Four growth reactions: $^{A}\mathbf{n} + 4(^{2}\mathrm{H}) \rightarrow ^{A+4}\mathbf{n} + 4(^{1}\mathrm{H})$ One alpha decay and <sup>A</sup>**n** catalyst restored: **Overall**: $4(^{2}H) \rightarrow 4(^{1}H) + ^{4}He + 21 \text{ MeV}$ 6. Transmutation Neutron transfer reactions lead to transmutation. As an example:

Two beta decays:

(<sup>27</sup>Mg and <sup>27</sup>Al are ionized and electrons carry kinetic energy.)

**Overall**:  $^{A}n + {}^{23}Na \rightarrow {}^{A-4}n + {}^{27}Al + (10+12) \text{ MeV}.$  $^{23}$ Na  $\rightarrow ^{27}$ Al (agrees with Iwamura).

trated

ium

into it. Bubble

ain in lear

# **Data**: From Fig. 5 of Focardi, Habel, and Piantelli (1994).

Equipment

A gas-tight oven containing (1) hydrogen gas, (2) a nickel rod surrounded by an electric heater, and (3) a thermocouple for measuring rod temperature.

## The equipment is not a calorimeter.

## Procedure

A stable relationship is established between input heater power and rod temperature, for temperatures up to about 400°C.

(see "unloaded Ni rod" in figure)

The temperature is raised above 400°C for a period of time, during which hydrogen is absorbed by the nickel rod.

The high-temperature treatment produces

irreversible change.

A new stable relationship between heater power and temperature has been established for the hydrogen loaded rod.

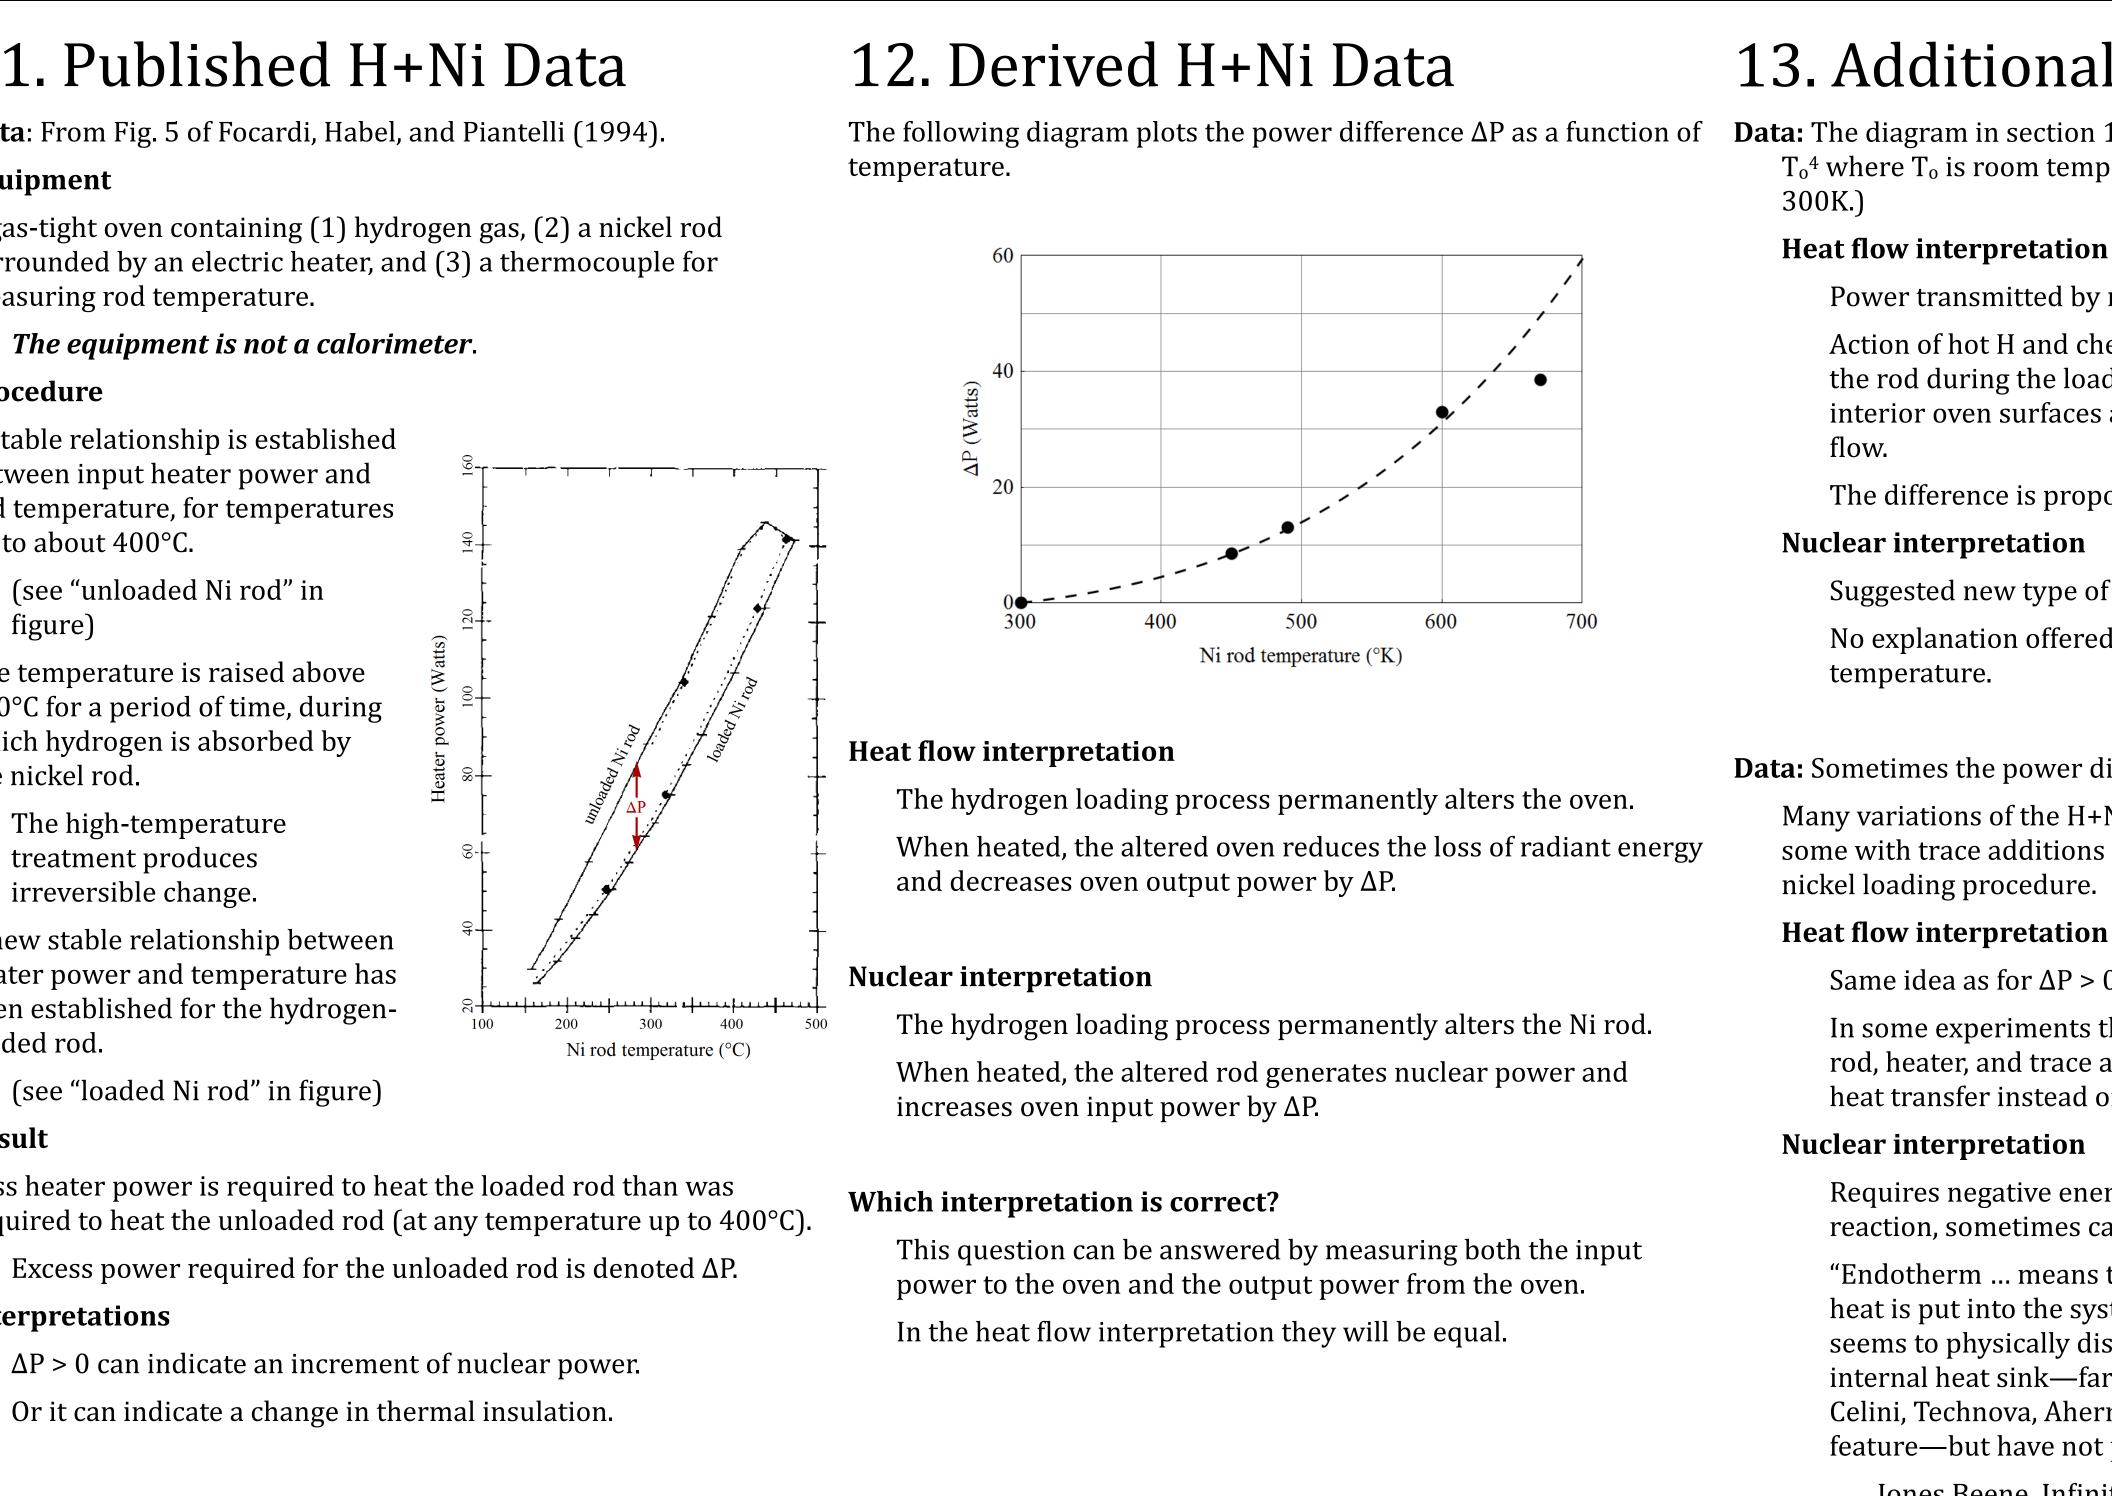

(see "loaded Ni rod" in figure)

## Result

Less heater power is required to heat the loaded rod than was required to heat the unloaded rod (at any temperature up to 400°C).

### Interpretations

 $\Delta P > 0$  can indicate an increment of nuclear power. Or it can indicate a change in thermal insulation.

Convection? Boiling hot spot? Research opportunity.

Mizuno fluid shear makes the difference.

## 13. Additional Considerations

**Data:** The diagram in section 12 shows that  $\Delta P$  is proportional to T<sup>4</sup> –  $T_0^4$  where  $T_0$  is room temperature. (In this experiment  $T_0 =$ 

Power transmitted by radiation is proportional to T<sup>4</sup>. Action of hot H and chemicals emitted from the heater and the rod during the loading process can bleach and whiten interior oven surfaces and decrease the rate of radiant energy

The difference is proportional to T<sup>4</sup>.

- Suggested new type of nuclear power.
- No explanation offered for dependence of power on

**Data:** Sometimes the power difference is negative ( $\Delta P < 0$ ). Many variations of the H+Ni experiment have been performed, some with trace additions of materials to alter the nature of the

Same idea as for  $\Delta P > 0$ .

In some experiments the action of hot H and chemicals from rod, heater, and trace additions increase the rate of radiant heat transfer instead of decreasing it, changing the sign of  $\Delta P$ .

Requires negative energy release from spontaneous nuclear reaction, sometimes called endotherm:

"Endotherm ... means that when a large amount of outside heat is put into the system, a substantial fraction of that heat seems to physically disappear, as if there was a magical internal heat sink—far surpassing any chemical explanation. Celini, Technova, Ahern and others have seen this physical feature—but have not pursued it."

Jones Beene, Infinite Energy 18, No. 108. (2013) p29.
